ABSTRACT

Machine Learning is a category of algorithms that allows software applications to become more accurate in predicting outcomes without being explicitly programmed. The basic premise of machine learning is to build models and employ algorithms that can receive input data and use statistical analysis to predict an output while updating outputs as new data becomes available. These models can be applied in different areas and trained to match the expectations of management so that accurate steps can be taken to achieve the organization's target. In this paper, the case of Big Mart, a one-stop-shopping-center, has been discussed to predict the sales of different types of items and for understanding the effects of different factors on the items' sales. Taking various aspects of a dataset collected for Big Mart, and the methodology followed for building a predictive model, results with high levels of accuracy are generated, and these observations can be employed to take decisions to improve sales.

Keywords: Machine Learning, Sales Prediction, Big Mart, Random Forest, Linear Regression

1. INTRODUCTION

In today's modern world, huge shopping centers such as big malls and marts are recording data related to sales of items or products with their various dependent or independent factors as an important step to be helpful in prediction of future demands and inventory management. The dataset built with various dependent and independent variables is a composite form of item attributes, data gathered by means of customer, and also data related to inventory management in a data SALES PREDICTION 4 warehouse. The data is thereafter refined in order to get accurate predictions and gather new as well as interesting results that shed a new light on our knowledge with respect to the task's data. This can then further be used for forecasting future sales by means of employing machine learning algorithms such as the random forests and simple or multiple linear regression model.

2. REVIEW-1 (Survey & Analysis)

The data available is increasing day by day and such a huge amount of unprocessed data is needed to be analysed precisely, as it can give very informative and finely pure gradient results as per current standard requirements. It is not wrong to say as with the evolution of Artificial Intelligence (AI) over the past two decades, Machine Learning (ML) is also on a fast pace for its evolution. ML is an important mainstay of IT sector and with that, a rather central, albeit usually hidden, part of our life. As the technology progresses, the analysis and understanding of data to give good results will also increase as the data is very useful in current aspects. In machine learning, one deals with both supervised and unsupervised types of tasks and generally a classification type problem accounts as a resource for knowledge discovery. It generates resources and employs regression to make precise predictions about future, the main emphasis being laid on making a system self-efficient, to be able to do computations and analysis to generate much accurate and precise results. SALES PREDICTION 5 By using statistic and probabilistic tools, data can be converted into knowledge. The statistical inferencing uses sampling distributions as a conceptual key.

ML can appear in many guises. In this paper, firstly, various applications of ML and the types of data they deal with are discussed. Next, the problem statement addressed through this work is stated in a formalized way. This is followed by explaining the methodology ensued and the prediction results observed on implementation. Various machine learning algorithms include:

- Linear Regression: It can be termed as a parametric technique which is used to predict a continuous or dependent variable on basis of a provided set of independent variables. This technique is said to be parametric as different assumptions are made on basis of data set.
- · K-Nearest Neighbors (KNN): It is a learning algorithm which is based on

instances and knowledge gained through them. Unlike mining in data stream scenarios, cases where every sample can simultaneously belong to multiple classes in hierarchical multi-label classification problems, k-NN is being proposed to be applied to predict outputs in structured form.

- Decision tree: It is an intuitive model having low bias and it can be adopted to build a classification tree with root node being the first to be taken into account in a top-down manner. It is a classic model for machine learning.
- Naïve Bayes classifiers: These are based on Bayes theorem and a collection of classification algorithms where classification of every pair is independent of each other. Bayesian learning can provide SALES PREDICTION 6 predictions with readable reasons by generating an if-then form of list of rules.
- Random Tree: It is an efficient algorithm for achieving scalability and is used in identification problems for building approximate system. The decisions are taken considering the choices made on basis of possible consequences, the variables which are included, input factor. Other algorithms can include SVM, xgboost, logistic regression and so on.
- K-means clustering: This algorithm is used in unsupervised learning for creating clusters of related data based on their closeness to the centroid value.

3. REVIEW-2 (Requirement gathering & Prototype Design)

To find out what role certain properties of an item play and how they affect their sales by understanding Big Mart sales." In order to help Big Mart achieve this goal, a predictive model can be built to find out for every store, the key factors that can increase their sales and what changes could be made to the product or store's characteristics.

Python is a general purpose, interpreted-high level language used extensively nowadays for solving domain problems instead of dealing with complexities of a system. It is also termed as the 'batteries included language' for programming. It has various libraries used for scientific purposes and inquiries along with number of third-party libraries for making problem solving efficient.

In this work, the Python libraries of Numpy, for scientific computation, and Matplotlib, for 2D plotting have been used. Along with this, Pandas tool of Python has been employed for carrying out data analysis. Random forest regressor is used to solve tasks by ensembling random forest method. As a development platform, Jupyter Notebook, which proves to work great due to its excellence in 'literate programming', where human friendly code is punctuated within code blocks, has been used.

4. REVIEW-3 (Evaluation)

In this section, the programming language, libraries, implementation platform along with the data modeling and the observations and results obtained from it are discussed. SALES PREDICTION 8

R Squared value = 0.5867640914432671

5. CONCLUSION

Sales prediction is a critical part of the strategic planning process and allows a company to predict how their company will perform in the future. It allows them to not only plan for new opportunities, but also allows them to avert negative trends that appear in the forecast. A mission statement is important because it allows an organization to know exactly why they exist and serves as a guide for decisions. Both concepts are important to the success of the company and should not be overlooked throughout the strategic planning process.
